

Once you cloned the repository and opened it in Visual Studio, you should see all the code. You can go ahead and look through it and make changes just to play with it. When you want to run it, click on the green okay button at the top (seen below). The filled icon represents “running with a Debugger” and the outlined, empty one is without a debugger. A debugger is basically a command line that pops up when you run it and it helps you catch errors early on.

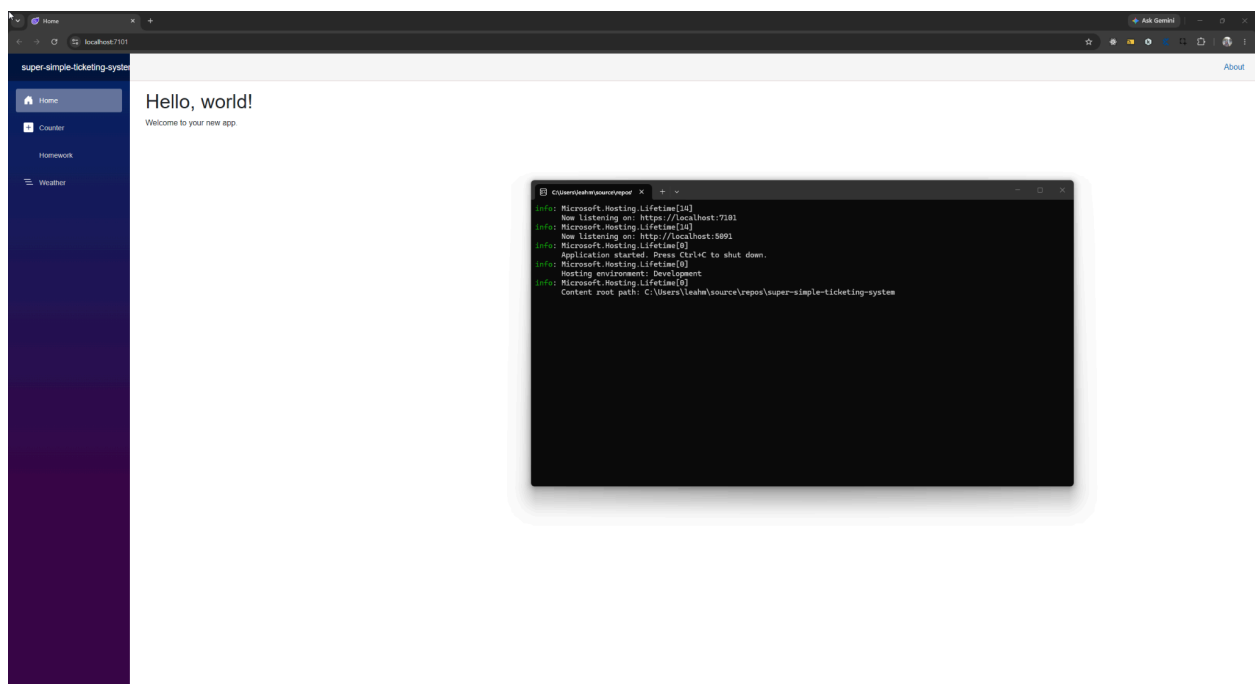

This project was configured to use SSL. If you haven't run anything that uses SSL on your PC before using Visual Studio's .NET you will probably get this warning. Click “Yes”

You will also get this afterwards. This is just having you trust the self-signed cert that Visual Studio generated. Click “Yes”

From there, you should now see your project. (Yours will look slightly different with more wording because I took this screenshot earlier). Mine is run with the debugger, notice the Command Line. Without the debugger, that will not appear – which is fine.

Now get to work.
